**Ilex aquifolium** in Europe: distribution, habitat, usage and threats

N. Guerrero Hue, G. Caudullo, D. de Rigo

The European holly (*Ilex aquifolium* L.) is an evergreen small tree or shrub, with characteristic **conic** dark green leaves with spines and red berry fruits. Holly grows in Western Europe, Western Balkans and North Turkey up to the Caucasus, preferring Atlantic climates. It adapts to different soil conditions, occurring mainly as understorey vegetation in oak and beech temperate forests. It is widely planted as an ornamental plant and hedge shrub, and is also well known for Christmas decorations. Various fungi of genus **Phytophthora** cause roots to rot in cultivated hollies. However there are no critical threats for the conservation of this species.

### Distribution

This species occurs in Western Europe, from Spain to western Norway, North-West Africa in the Atlas Mountains, western Balkan Peninsula, North Turkey up to the Caucasus. It grows in northern ranges at sea level, up to 2600 m in Morocco. It is widely planted outside its natural range as an ornamental shrub in Europe and in other continents. On the west coast of the United States it is considered an invasive plant. Its distribution range is now starting to move over Europe, as a consequence of increased winter temperatures in northern regions and drought in the south, and in Scandinavia its range is beginning eastwards due to the hybridisation of native with ornamental genotypes.

### Habitat and Ecology

The holly grows in Atlantic and sub-Atlantic climates, also in a sub-Mediterranean climate at higher elevations, characterised by mild winter temperatures, relatively high summer precipitation and limited temperature ranges. This species is very plastic, growing in a wide variety of soil moistures and pH, but grows best in acid conditions. Regarding light tolerance, holly is a semi-shade species while in Mediterranean climates it is an obligate shade plant. It is a slow-growing species with a lifespan of 300 years in optimal conditions. Reproduction takes place mostly by seed, however vegetative regeneration (suckers and adventitious roots) may be important within dense holly formations. This species occurs within different plant communities, mainly as an understorey tree or in edges of temperate deciduous forests and woodlands dominated by oaks (*Quercus robur*, *Quercus petraea*, *Quercus pubescens*) or beech (*Fagus sylvatica*). In the Mediterranean region it can be found in evergreen oak forests (*Quercus ilex*) in the scrub communities.

### Importance and Usage

Holly is cultivated as an ornamental shrub, appreciated for the contrast between its dark green permanent foliage and the red fruits and traditionally used for Christmas decoration. Many varieties and hybrids have been developed for garden use; e.g. *Argentea Marginata* with white-edged leaves, *Bacciflava* almost spineless and with yellow fruits. Holly is often used in heaths as it has spiny leaves, bears pruning well and it grows slowly. Since it is a dioecious species, commercial hollies usually have grafted female or male branches to produce fruit from a single plant. The wood of holly is greyish white, hard, heavy and with a strong fragrance. Its seeds ripen in late autumn and usually last throughout the winter, when birds, rodents and larger herbivores eat them.

### Field data in Europe (including absences)

<tr>
<th>Threats and Diseases</th>
</tr>
</thead>
<tbody>
<tr>
<td>There are no critical diseases affecting the European holly in its natural habitat. Principally they are recorded for the ornamental plants in gardens and parks. Among the phytophagous insects, the most known is the holly leaf miner (<em>Phytomyza ilicis</em>): a fly whose larva burrows into leaves. The fungus <em>Phytophthora ilicis</em> causes black leaf spots and then cankers and shoot dieback. The holly tree is host for other <em>Phytophthora</em> fruit rot and dieback fungi, such as <em>Phytophthora cinnamomi</em> and <em>Phytophthora psychrophila</em>.</td>
